Objective: To gather data on morbidity in Hong Kong women following childbirth. Method: A prospective repeated measures design was performed at weeks two and eight on a convenience sample of 20 women after childbirth. Results: The pilot study showed that at 8 weeks after childbirth many women were experiencing disorders they perceived to have a considerable adverse effect upon their daily life. Few women sought professional help for these disorders. Conclusion: The results of the pilot study indicate an undercurrent of ill-health in Hong Kong women during at least the first few months following childbirth and possibly a lot longer than this. Further research is required to follow-up women over a longer time to determine the prevalence and extent of postpartum problems so that appropriate health promotion, prevention and interventions may be planned and provided to these women.
